100 *Performance*

ENGR 3410 - Computer Architecture

Mark L. Chang

Fall 2006

Why are you here?

- Time travel

2) Build Computin

@ Profit.

- Remired. - Contons.

- Mark is

What is Computer Architecture?

_ Transistors

CS Archiocon (icando

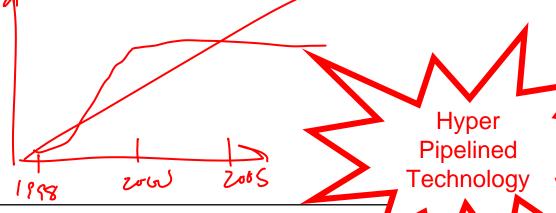

What things are important when buying a computer?

What features do you look for when buying one?

Standards Logos (flushy ones) reliability up gradabilit Size (mem) physical size

Computer "Performance"

- MIPS (Million Instructions Per Second) vs. MHz (Million Cycles Per Second)
- Throughput (jobs/seconds) vs. Latency (time to complete a job)
- Measuring, Metrics, Evaluation what is "best"?

3.09 GHz Pentium 4

The PowerBook G4 outguns Pentium III-based notebooks by up to 30 percent.*

* Based on Adobe Photoshop tests comparing a 500MHz PowerBook G4 to 850MHz Pentium III-based portable computers

Performance Example: Planes

Airplane	Passenger Capacity	Cruising Range (miles)	Cruising Speed (mph)	Passenger Throughput (passengermile/hour)
Boeing 777	375	4630	610	228,750
Boeing 747	470	4150	610	286,700
Concorde	132	4000	1350	178,200
Douglas DC8	146	8720	544	79,424

- Which is the "best" plane?
 - Which gets one passenger to the destination first?
 - Which moves the most passengers?
 - Which goes the furthest?
- Which is the "speediest" plane (between Seattle and NY)?
 - Latency: how fast is one person moved?
 - Throughput: number of people per time moved?

Computer Performance

• Primary goal: execution time (time from program start to program completion)

$$Performance = \frac{1}{ExecutionTime}$$

To compare machines, we say "X is n times faster than Y"

$$n = \frac{Performance_x}{Performance_y} = \frac{ExecutionTime_y}{ExecutionTime_x}$$

• Example: Machine *Orange* and *Grape* run a program Orange takes 5 seconds, Grape takes 10 seconds

Orange is _____times faster than Grape

Execution Time

- Elapsed Time
 - counts everything (disk and memory accesses, I/O, etc.)
 - a useful number, but often not good for comparison purposes
- CPU time
 - doesn't count I/O or time spent running other programs
 - can be broken up into system time, and user time
- Example: Unix "time" command

```
fpga.olin.edu> time javac CircuitViewer.java
3.370u 0.570s 0:12.44 31.6%
```

- Our focus: user CPU time
 - time spent executing the lines of code that are "in" our program

CPU Time

CPU execution time CPU clock cycles Clock period for a program for a program

CPU execution time CPU clock cycles * Clock rate for a program for a program

Application example:

A program takes 10 seconds on computer *Orange*, with a 400MHz clock. Our design team is developing a machine *Grape* with a much higher clock rate, but it will require 1.2 times as many clock cycles. If we want to be

able to run the program in 6 seconds how fast must the clock rate be?

ORANGE: $10s = \frac{N \text{ cycles}}{400 \text{ cycles}/s}$ No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be?

No explain the program in 6 seconds how fast must the clock rate be? N = 4000 × 10° cv

X = 800 MHZ = X

CPI

• How do the # of instructions in a program relate to the execution time?

CPU clock cycles for a program = Instructions for a program * Average Clock Cycles per Instruction (CPI)

CPU execution time for a program = Instructions * CPI * Clock rate

CPI Example

- Suppose we have two implementations of the same instruction set (ISA).
- For some program

Machine A has a clock cycle time of 10 ns. and a CPI of 2.0 Machine B has a clock cycle time of 20 ns. and a CPI of 1.2

What machine is faster for this program, and by how much?

CPUTIME_A =
$$I \times 2.0 \times 10us = 20 \times Fns$$

CPUTIME_B = $I \times 1.2 \times 20ns = 24 \times Ins$
A is $\frac{24}{20}$ = $1.2 \times fastn$

Computing CPI

- Different types of instructions can take very different amounts of cycles
- Memory accesses, integer math, floating point, control flow

$$CPI = \sum_{types} \left(Cycles_{type} * Frequency_{type} \right)$$

Instruction Type	Type Cycles	Type Frequency	Cycles * Freq
ALU	1	50%	. 5
Load	5	20%	/1 O
Store	3	10%	• 3
Branch	2	20%	. 4
		CPI:	2.2

CPI & Processor Tradeoffs

Instruction Type	Type Cycles	Type Frequency
ALU	1	50%
Load	5	20%
Store	3	10%
Branch	2	20%

How much faster would the machine be if:

1. A data cache reduced the average load time to 2 cycles?

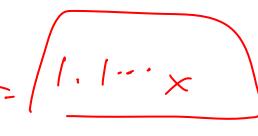

2. Branch prediction shaved a cycle off the branch time?

$$CPI_{rew} = 2.0 \qquad \frac{2.2}{2} =$$

$$\frac{2\cdot 2}{2} = \boxed{\frac{1\cdot l_{x}}{2}}$$

3. Two ALU instructions could be executed at once?

Warning 1: Amdahl's Law

The impact of a performance improvement is limited by what is NOT improved:

Execution time after improvement = Execution time to fundament = Execution time to fundament = Execution time to fundament to fundament

 Example: Assume a program runs in 100 seconds on a machine, with multiply responsible for 80 seconds of this time. How much do we have to speed up multiply to make the program run 4 times faster?

$$(255)$$
 $255 = 205 + 805 \times 1$
 $N = 80/5$

5 times faster?

Warning 2: MIPs, MHz ≠ Performance

• Higher MHz (clock rate) doesn't always mean better CPU Orange computer: 1000 MHz, CPI: 2.5, 1 billion instruction program

$$T = \frac{18 \times 2.5}{100} = 2.55$$

Grape computer: 500MHz, CPI: 1.1, 1 billion instruction program

$$T = \frac{18 \times 1.1}{500} = 2.25$$

 Higher MIPs (million instructions per second) doesn't always mean better CPU

1 MHz machine, with two different compilers

Compiler A on program X: 10M ALU, 1M Load

Compiler B on program X: 5M ALU, 1M Load

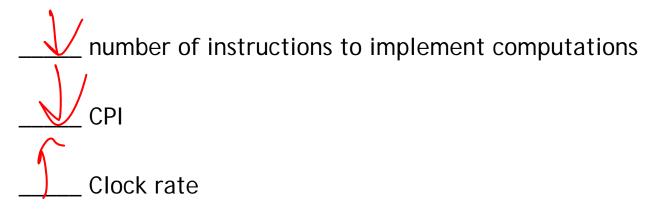

Execution Time: A 155 B 105

Instruction Type	Type Cycles
ALU	1
Load	5
Store	3
Branch	2

Processor Performance Summary

• Machine performance:

• Better performance:

 Improving performance must balance each constraint Example: RISC vs. CISC
